

SEMINAR ON MODULI THEORY

September 3, 2020

NEERAJ DESHMUKH

These are notes for the first few lectures. The aim is to gather sufficient algebraic geometry background for discussing moduli theory. A lot of L^AT_EX code in this document has been shamelessly copied from the stacks project repository on GitHub¹

1. SCHEMES

For the sake of completeness we begin by reviewing the definition of a locally ringed space.

Definition 1.1. Locally ringed spaces.

- (1) A *locally ringed space* (X, \mathcal{O}_X) is a pair consisting of a topological space X and a sheaf of rings \mathcal{O}_X all of whose stalks are local rings.
- (2) Given a locally ringed space (X, \mathcal{O}_X) we say that $\mathcal{O}_{X,x}$ is the *local ring of X at x* . We denote $\mathfrak{m}_{X,x}$ or simply \mathfrak{m}_x the maximal ideal of $\mathcal{O}_{X,x}$. Moreover, the *residue field of X at x* is the residue field $\kappa(x) = \mathcal{O}_{X,x}/\mathfrak{m}_x$.
- (3) A *morphism of locally ringed spaces* $(f, f^\#) : (X, \mathcal{O}_X) \rightarrow (Y, \mathcal{O}_Y)$ is a morphism of ringed spaces such that for all $x \in X$ the induced ring map $\mathcal{O}_{Y,f(x)} \rightarrow \mathcal{O}_{X,x}$ is a local ring map.

We know that affine schemes are locally ringed spaces: we take $\text{Spec } R$ with the zariski topology and for any principal open set $D(f)$ we assign the ring R_f . So, any ring R produces the sheaf \widetilde{R} on $\text{Spec } R$. This is called the tilde construction. (sanity check: if you can do this, then you should be able to construct a sheaf on $\text{Spec } R$ for any R -module M).

Definition 1.2. A *scheme* is a locally ringed space with the property that every point has an open neighbourhood which is an affine scheme. A *morphism of schemes* is a morphism of locally ringed spaces. The category of schemes will be denoted Sch .

Definition 1.3. Let (X, \mathcal{O}_X) be a scheme. A sheaf of modules on X is a sheaf \mathcal{F} on X such that for every open set U , $\mathcal{F}(U)$ is an $\mathcal{O}_X(U)$ -module. We say that a sheaf of modules \mathcal{F} is *quasi-coherent* if for every affine open $U \simeq \text{Spec}(R)$, the sheaf $\mathcal{F}|_U$ on U is of the form \widetilde{M} for some R -module M .

Make special note of the next lemma. This basically lets us reduce problems about schemes to statement about affine schemes (ergo, ring theory), whenever the problem at hand is of a *local* nature. Ravi Vakil calls this *affine communication lemma*.

Lemma 1.4. Let X be a scheme. Let P be a local property of rings. The following are equivalent:

- (1) The scheme X is locally P .
- (2) For every affine open $U \subset X$ the property $P(\mathcal{O}_X(U))$ holds.
- (3) There exists an affine open covering $X = \bigcup U_i$ such that each $\mathcal{O}_X(U_i)$ satisfies P .

¹Thank you Aise Johan de Jong *et al.* for TeX-ing all that math!

- (4) There exists an open covering $X = \bigcup X_j$ such that each open subscheme X_j is locally P .

Moreover, if X is locally P then every open subscheme is locally P .

This is how commutative algebra meets geometry. Often, the properties that we want to consider are “globalised” versions of statements about rings.²

1.1. Two ways of Gluing $\mathbb{A}^1 \setminus \{0\}$. Take two copies of $\mathbb{A}^1 := \operatorname{Spec} k[x]$ ³. Let $U := \operatorname{Spec} k[x, 1/x]$, be the complement of the origin in \mathbb{A}^1 .

$$\begin{array}{ccc} \mathbb{A}^1 & & \mathbb{A}^1 \\ \uparrow & & \uparrow \\ U & \xrightarrow{\sim} & U \end{array}$$

Giving this information is that same giving a scheme which is looks like \mathbb{A}^1 around every point (why?). We consider two possible choices for the identification on U :

$$\begin{aligned} x &\mapsto x \\ x &\mapsto 1/x \end{aligned}$$

Example 1.5. The first choice gives us a scheme which is like \mathbb{A}^1 everywhere except at the origin where it is now two points instead of one. Notice that the ring of global section of this scheme is $k[x]$ (a global section is same as giving polynomials $f, g \in k[x]$, one for each copy of \mathbb{A}^1 which are equal on U ; conclude from this).

Example 1.6. The second choice gives us the projective line \mathbb{P}^1 . This is looks like \mathbb{A}^1 with “a point added at infinity”. We will now compute its global sections.

Let $f, g \in \mathbb{A}^1$ be two polynomials such that $f(x) = g(1/x)$ in $k[x, 1/x]$. Then straightforward algebra shows that this can happen only when f, g are constant, i.e., $\Gamma(\mathbb{P}^1, \mathcal{O}_{\mathbb{P}^1}) = k$.

1.2. A DVR with double origin. Similar to \mathbb{A}^1 with double origin, we can glue two copies of a DVR. Let R be a discrete valuation ring. Then $\operatorname{Spec} R$ has exactly two point: the generic point (zero ideal) and the closed point (maximal ideal). The generic point is open in $\operatorname{Spec} R$ and is given by $\operatorname{Spec} K$, where K is quotient field of R . As for \mathbb{A}^1 , the ring of global sections of a DVR with double origin is R .

Furthermore, any coherent sheaf (a quasi-coherent sheaf which is a finitely generated module on each copy of R) is determined by a pair (n, T) where n is a positive integer and $T \in GL_n(K)$. Since R is a principal ideal domain, any finitely generated R -module M is a direct sum of its free and torsion parts. Thus, if M, N are two finitely generated R -modules, there exists an isomorphism (given by a K -linear map) $M \otimes K \simeq N \otimes K$ if and only if the rank of their free parts is the same.

1.3. P versus locally P . All the above are examples of locally normal (in fact, regular), locally reduced and locally Noetherian scheme⁴. For any property that is locally P (as defined in 1.4), the usual rule of thumb for nomenclature is $P = \text{locally } P + \text{quasi-compact}$: for example, a scheme is Noetherian if it is locally Noetherian and quasi-compact. Not all

²You can also “globalise” morphisms of rings, but now you have two schemes to work locally on. We’ll do this soon.

³For simplicity, assume that k is field, but this is not needed.

⁴This is probably not standard notation, but instructive for the current discussion.

properties are of this type: for example quasi-compactness, separatedness, properness, etc. We will come back to this when we discuss morphisms.

1.4. Line Bundles on \mathbb{P}^1 : Locally on an affine open, this should be a free module of rank one. Let's construct one such line bundle (non-trivial, of course): There are two open sets, $D(x)$ and $D(y)$, on these our line bundle looks like $k[x]$ and $k[y]$, respectively. Now, how do they glue on $k[x, 1/x] \simeq k[y, 1/y]$? Let's use the map which sends $\phi(1) : f(x) \mapsto f(x)y$, since y is $1/x$ in this ring, we see that the global sections are linear polynomials. You construct such a map $\phi(n)$ for every power of y . That will give you degree n monomials. These line bundles are called $\mathcal{O}(n)$'s. Playing around with the algebra of the maps $\phi(n)$ a little will show that these line bundles satisfy relations like $\mathcal{O}(n) \otimes \mathcal{O}(m) \simeq \mathcal{O}(m+n)$, and admit duals which are denoted by $\mathcal{O}(-n)$.⁵ [Discussed till here as of August 28, 2020]

1.5. A slightly more involved scheme: \mathbb{P}^n . Consider

$$D(x_i) := \operatorname{Spec} k[x_{0/i}, x_{1/i}, \dots, x_{n/i}] / (x_{i/i} - 1).$$

This is basically the same as \mathbb{A}^n , but we write it like this for reasons that will become evident soon. If we invert one of the variables, say $x_{j/i}$, we can write an isomorphism $D(x_i)_{x_{j/i}} \cong D(x_j)_{x_{i/j}}$ given by the maps

$$\phi_{ij} : x_{k/i} \mapsto x_{k/j} / x_{i/j} \quad \& \quad \phi_{ji} : x_{k/j} \mapsto x_{k/i} / x_{j/i}$$

Now we just have to check that this agrees on triples. For this, you just have to check that $\phi_{ij} \circ \phi_{jk} = \phi_{ik}$ (what is the (co)domain of these maps?). Note that this construction doesn't really utilise the fact that k is a field.

1.6. A classical interlude. Here's a classical definition of \mathbb{P}^n in terms of *homogeneous coordinates*. Let k be a field. Consider $k^{n+1} \setminus (0, 0, \dots, 0)$. We define \mathbb{P}^n to be:

$$\mathbb{P}^n := \{(x_0, x_1, \dots, x_n) \mid (x_i) \simeq (y_i) \text{ if there is a } \lambda \in k^\times \text{ such that for all } i, x_i = \lambda y_i\}$$

We denote the equivalence class of the tuple (x_i) by $[x_0 : x_1 : \dots : x_n]$. These are called homogeneous coordinates. If we assume one of the coordinates to be non-zero, say x_i , then we can divide the entire tuple by it. This gives us a set, $D(x_i) := \{[x_0/x_i : x_1/x_i : \dots : 1 : \dots : x_n/x_i]\}$. It is easy to see that this set is in bijection with k^n . Set $x_k/x_i := x_{k/i}$ ⁶, then tuples in $D(x_i)$ look like $[x_{0/i} : x_{1/i} : \dots : 1 : \dots : x_{n/i}]$. This $D(x_i)$ should be thought of as the complement of the hyperplane defined by x_i (which is actually a projective space of one dimension less).

If an x_j is non-zero, for a j distinct from i , then we can divide by it. This gives us the relation, $x_{k/i}/x_{j/i} = x_{k/j}$. This is the origin of the morphisms ϕ_{ij} above⁷. Homogenisation and de-homogenisation(?).

⁵The line bundle $\mathcal{O}(1)$ is important. To say that a variety is projective, we need to show that something like $\mathcal{O}(1)$ lives on it. Actually, some lesser works, but we will come back to this later.

⁶This notation is meant to be suggestive.

⁷If you have seen the construction of Grassmannians as smooth manifolds, the same construction also goes through in algebraic geometry.

1.7. Proj of a graded ring. Now that we have defined \mathbb{P}^n , I want to motivate the proj construction for graded rings using the example of \mathbb{P}^n . In a sense, this construction is not very different from the gluing construction above. However, it gives us more control over the algebra and sheaf theory of \mathbb{P}^n and its subschemes. For example, every closed subscheme of \mathbb{P}^n comes from a graded ideal (this is a neat analogue of the affine case). Another advantage is that it lets us talk about affine open covers given by the complements of non-linear hypersurfaces. This can be useful when dealing with closed subschemes of \mathbb{P}^n , but then we won't need to make any choices about what affine covers should be.

Consider the ring $S_\bullet := k[x_0, x_1, \dots, x_n]$, now thought of as a graded ring with the grading given by degrees of monomials. The degree of a monomial $x_{i_1}^{r_1} \dots x_{i_m}^{r_m}$ is the integer $r_1 + \dots + r_m$. The constants have degree zero. We can write our ring as $S_\bullet = \bigoplus_{i \geq 0} S_i$, where each S_i is the homogeneous component of degree i . Note that S_\bullet is generated by the elements x_i 's as an S_0 -algebra (here, S_0 is k). The ideal generated by the x_i 's is just $S_+ = \bigoplus_{i > 0} S_i$. This is just the ideal (x_0, \dots, x_n) written by keeping track of the grading. We will call this the irrelevant ideal. Then, proj of the graded ring S_\bullet , $\text{Proj}(S_\bullet)$ is the set of those homogeneous prime ideals which do not contain S_+ . This inherits a Zariski topology from $\text{Spec } S_\bullet$. We can then check that this is a scheme by producing affine open covers using the homogeneous elements. The resulting scheme is \mathbb{P}^n .

This can be a bit tricky to write down when the homogeneous elements have large degrees. But to give you a flavour of what is going on, let's examine what this is in for \mathbb{P}^1 . We have already seen a description of \mathbb{P}^1 above, by gluing $\mathbb{A}^1 \setminus 0$ in an "inverse fashion". By the above discussion, $\mathbb{P}^1 := \text{Proj } k[x, y]$. Here's a slightly different description of \mathbb{P}^1 using degree 2 hypersurfaces. Consider the homogeneous ideal (x^2, xy, y^2) . Localise $k[x, y]$ with respect to x^2 . This gives us a graded ring $(S_\bullet)_{x^2} = k[x, y]_{x^2}$, where $1/x^2$ has degree -2 . Thus, elements here are of the form $f(x, y)/(x^2)^N$ and can have negative degrees. Look at the zero graded piece of this ring which we will denote by the horrible notation, $((S_\bullet)_{x^2})_0$. This ring can be described as,

$$((S_\bullet)_{x^2})_0 = k[y/x].$$

This is just the ordinary polynomial ring in the variable ' y/x '. So, $\text{Spec } ((S_\bullet)_{x^2})_0 = \mathbb{A}^1$. Similarly, inverting the elements xy and y^2 in S_\bullet and looking at the zeroth graded pieces gives us the polynomial rings,

$$\begin{aligned} ((S_\bullet)_{y^2})_0 &= k[x/y] \longleftrightarrow \mathbb{A}^1 \\ ((S_\bullet)_{xy})_0 &= k[x/y, y/x] \longleftrightarrow \mathbb{A}^1 \setminus 0. \end{aligned}$$

The radical of the ideal (x^2, xy, y^2) contains the irrelevant ideal (why?). This implies that every homogeneous prime ideal is contained in one of the above three affine pieces. Thus, this gives us a covering of \mathbb{P}^1 .

If instead we invert degree one element x and y , the zeroth graded pieces of these localisations look like,

$$\begin{aligned} ((S_\bullet)_x)_0 &= k[x/y] \longleftrightarrow \mathbb{A}^1 \\ ((S_\bullet)_y)_0 &= k[y/x] \longleftrightarrow \mathbb{A}^1. \end{aligned}$$

This will then recover our original construction of \mathbb{P}^1 .

Caution: While using affine opens corresponding to degree 2 element, it may seem like it should be sufficient to just invert x^2 , and y^2 to get an open cover of \mathbb{P}^1 . This is false! For example, the homogeneous ideal $(x - y)$ is not contained in the radical of (x^2, y^2) .

1.8. Some more examples.

- (1) An example of a non-Noetherian scheme is $\text{Spec } R[x_1, x_2, \dots]$.
- (2) $V_+(x^2 + y^2 + z^2)$ over \mathbb{R} and \mathbb{C} . Over \mathbb{C} , one have the following linear change of coordinates, $(x, y, z) \mapsto (x + iy, x - iy, iz)$. Then, $(x + iy)(x - iy) - z^2 = x^2 + y^2 + (iz)^2$. So, this is the same as $V_+(uv - z^2)$, which is the (2-fold-)Veronese embedding of \mathbb{P}^1 in \mathbb{P}^2 given by $[x : y] \mapsto [x^2 : xy : y^2]$. Similarly, the d -fold Veronese embedding is given by $[x : y] \mapsto [x^d : x^{d-1}y : \dots : xy^{d-1} : y^d]$.
- (3) Blow-up of \mathbb{A}^2 at the origin. This is described as

$$Y := \{((x, y), [X : Y]) \in \mathbb{A}^2 \times \mathbb{P}^1 \mid xY = yX\}$$

This comes with a projection map $p : Y \rightarrow \mathbb{A}^2$. Observe that outside the origin this is an isomorphism, i.e, $p^{-1}(\mathbb{A}^1 \setminus 0) = \mathbb{A}^1 \setminus 0$, and $p^{-1}(0) = \mathbb{P}^1$.

- (4) An example of a scheme without a closed point. This one is a involved but idea is as follows. There is a valuation on the polynomial ring (or power series ring?) in infinitely many variable, such that every non-maximal prime ideal is contained in a non-maximal prime ideal. Then, knocking off the maximal ideal gives a scheme without any closed point. This scheme is *not* quasi-compact.

2. MORPHISMS

As mentioned before, many of the properties of morphisms that we are interested in are “globalised” versions of properties of ring maps. However, we have to first say what it means for morphism of schemes to be a local property. There are three kinds of local properties: local on the source, local on the target, local on the source and target. We will say what this means now:

Definition 2.1. Let \mathcal{P} be a property of morphisms of schemes. Let $f : X \rightarrow Y$ be a morphism which satisfies \mathcal{P} . Then,

- (1) We say that \mathcal{P} is *affine-local on the target* if given any affine open cover $\{V_i\}$ of Y , $f : X \rightarrow Y$ has \mathcal{P} if and only if the restriction $f : f^{-1}(V_i) \rightarrow V_i$ has \mathcal{P} for each i .
- (2) We say that \mathcal{P} is *affine-local on the source* if given any affine open cover $\{U_i\}$ of X , $X \rightarrow Y$ has \mathcal{P} if and only if the composite $U_i \rightarrow Y$ has \mathcal{P} for each i .

Using *affine communication lemma* one can then show that it suffices to check the above statements on single affine open cover.

An important maxim of Grothendieck was that instead of considering schemes in isolation, we should look at things relative to each other, i.e, everything should be seen as a property of morphisms. Then properties of schemes should really be thought of as properties of morphisms $X \rightarrow \text{Spec } \mathbb{Z}$ (or whatever base you are working over. For a lot of people it is the spectrum of a field). This is mostly true: many property of schemes can be turned into properties of morphisms of schemes⁸.

2.1. To be (or not to be) Noetherian. The discussion in 1.3 also applies to properties of morphisms, i.e., a morphism is said to be P if it is locally P and quasi-compact: a morphism is finite-type if it is locally finite type and quasi-compact; quasi-finite if it is locally quasi-finite and quasi-compact.

However, this is not true of finite presentation. A morphism is of finite presentation if it is locally of finite presentation, quasi-compact *and* *quasi-separated*. This is because, really,

⁸For example, affine opens form a basis for the topology on a scheme. Can this statment be “relativised” to affine morphisms $X \rightarrow Y$? I don’t know the answer.

finite presentation is a condition to correct for non-Noetherian-ness over arbitrary bases. Note that for Noetherian schemes, a morphism (locally) of finite type is automatically (locally) of finite presentation. Furthermore, quasi-separatedness is automatic for Noetherian scheme. There is a very nice discussion on mathoverflow on this that I encourage you to look up⁹.

Examples:

- (1) $x \mapsto x^2$ (more, generally x^n). This morphism is ramified at the origin (but unramified on $\mathbb{A}^1 \setminus \{0\}$), finitely presented, flat.
- (2) A non-quasi-compact open immersion. $\mathrm{Spec} k[x_1, x_2, \dots] \setminus \{(x_1, x_2, \dots)\} \hookrightarrow \mathrm{Spec} k[x_1, x_2, \dots]$ Polynomial ring in infinitely many variables and knock off the origin.
- (3) A finite morphism.
- (4) A smooth morphism. A non-smooth morphism (nodal curve over \mathbb{A}^1).
- (5) Open embeddings are locally of finite presentation¹⁰.
- (6) Open embedding is étale is fppf is fpqc.

⁹<https://mathoverflow.net/questions/36737/why-does-finitely-presented-imply-quasi-separated>

¹⁰This is not true in perfectoid geometry, which is quite sad.
